

phaC Sequence Evidence by Tier: Identity Drops, Coverage Mostly Doesn't

Numbers on each violin are the median. n = 30,810 / 2,947 / 9 / 14 / 0 targets with ≥ 1 hit (left to right).

% Identity to Best-Matching Audited Reference

Query Coverage to Best-Matching Audited Reference

Reference set = 1,723 InterPro-confirmed-genuine phaC references (PHA_CLEAN_RESULTS.md §2). Black box = interquartile range, white line = median.
The two unresolved tiers are now tiny (n=9 and n=14, versus tens of thousands in the strong-evidence tiers, see PHA_CLEAN_RESULTS.md section 3) -- read their violins as a handful of individual remaining cases, not a population estimate. Coverage stays high (~85%) even for these; identity is lower and more variable (median 36-51%) but not below the triad-complete tier's own lower spread -- consistent with divergent-but-real matches, not fragments.
