

Depth vs. phaC Cluster: the 10 Genera Found in Hadal Trenches (>6000m)

Each point is one genome; color = its phaC 70%-identity cluster (own palette per genus -- colors are not comparable across columns)

Dotted line = the >6000m hadal threshold used throughout this analysis. Where a column's points above and below that line share the same color, that genus's hadal phaC sits in the exact same 70%-identity cluster as its shallow-water relatives -- consistent with the mmseqs2 search finding (figures/phaC_nearest_known_identity_vs_depth.png) that hadal phaC is mostly not novel, just a depth-extreme sample of an existing lineage. QC: excludes 67 confirmed-wrong-gene phaC references + 1 known 102aa fragment (see module docstring).
