

Marinobacter-Dominant PhaC Clusters Are Cosmopolitan, Not Regional

6 of 19 clusters with Marinobacter as the dominant host genus qualify: ≥ 30 genomes AND $\text{geo_mean_resultant_length} < 0.4$ (of 6 large enough by genome count alone, several were more regionally concentrated and are excluded here). Each panel is one cluster's actual genome-level footprint (not a centroid). Contrast with the regional-specialist figure: those clusters had $\text{geo_mean_resultant_length} > 0.85$ (concentrated in one place); every cluster shown here has $R < 0.4$ — genuinely global, not local.
